Assignment 6- Hybrid MPI + MP + CUDA Programming
CSCI 596: Scientific Computing & Visualization

Anup V Kanale

November 1, 2017

The goal of this assignment is understand the basics of cuda through two examples– for calculating the pair distribution function, and to calculate π.

1 Task I– Pair-Distribution Computation with CUDA

The pair distribution function (PDF) is the probability of finding any two atoms, which are a given distance r apart, in a given volume. It is popularly used to measure the order, especially crystalline materials.

To compute the pdf, we fist calculate the histogram of atomic pair distances, i.e., calculate the distance between all pairs of atoms i and j, say r_{ij}, put them in the appropriate '*bins*' Δr to generate a histogram. Note that the maximum distance between pairs under periodic boundary condition is the diagonal of half the simulation box. The algorithm is as follows:

```
for all histogram bins i
   nhist[i] = 0
for all atomic pairs (i,j)
   ++nhist[r_ij/r]
```

Once this histogram is obtained, the pdf may then be computed using the following formula:

$$g(r_k) = \frac{\text{nhist}(k)}{2\pi r_k^2 \Delta r \rho N} \tag{1}$$

where r_k is the distance between two atoms, ρ is the number density of atoms, N is the total number of atoms. Notice that the obtaining the histogram involves computing distance between all pairs of atoms, which can get expensive with a large number of atoms. The parallel processing power of the GPUs was used to carry out these computations.

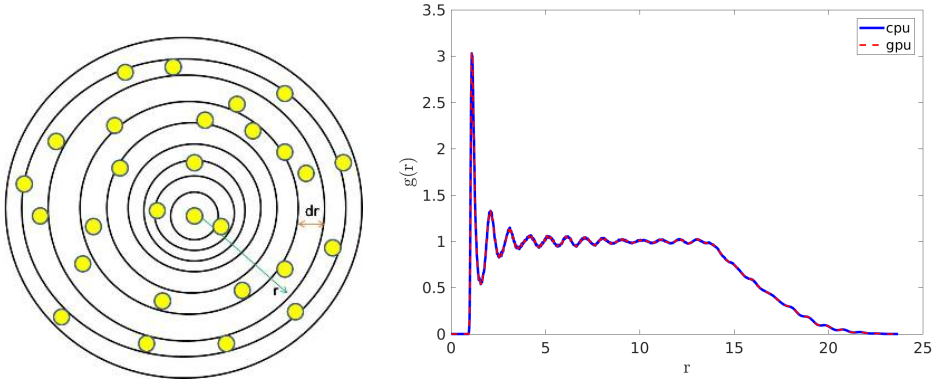

Figure 1: (a)Schematic for obtaining the histogram (b)PDF computation– CPU vs GPU

The code is attached in Appendix A. The pair distribution function computed using both the CPU and the GPUs shown for comparison in Fig 1 (the trailing off after $r = 14$ is explained in the notes.). The cpu implentation ran in 2.62 seconds whereas the gpu-parallel implementation ran in 0.28 seconds (almost 10 times faster!).

2 Task II– Parallel Computation of π using MPI+OMP+CUDA

In this part, a triple-decker MPI+OpenMP+CUDA program was written to compute the value of π, by modifying the double-decker MPI+CUDA program provided in class, described in the lecture note on "Hybrid MPI+OpenMP+CUDA Programming".

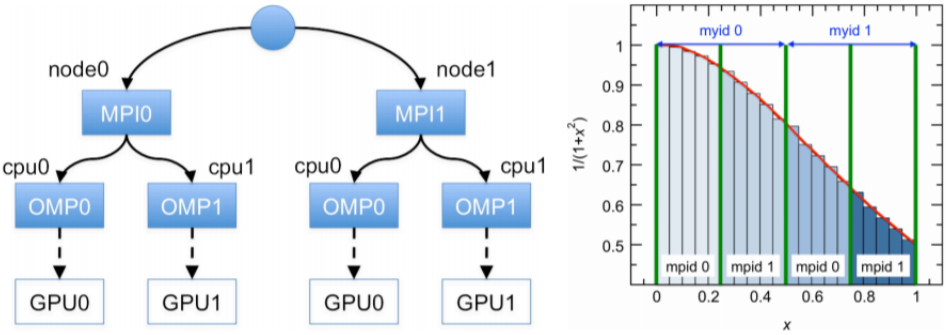

Figure 2: Output of program for computation of π

This program runs on two CPU cores, and 2 GPU devices on each compute node. This is achieved by launching one MPI rank per node, where each rank spawns two OpenMP threads, and each thread uses a different GPU device. This is illustrated in Fig 2. The above OpenMP multithreading introduces a race condition for variable pi. This can be circumvented by data privatization using `reduction(+:pi)`, which creates a `pi` variable for each thread. The '+:' means that the 'addition reduction' is to be performed on this variable.

The program can be found in appendix B, and the output of the program is as shown below in Fig 2. `myid` refers to the process rank, `mpid` is the thread number within the processor, and `device used` refers to the gpu.

```
[kanale@hpc3026 assgn6]$ mpirun -np 2 -machinefile nodefile ./pi --bind-to none
[hpc3026:44118] mca: base: component_find: unable to open /usr/usc/openmpi/1.6.4/lib/openmpi/mca_btl_mx: libmyriexpress.
so: cannot open shared object file: No such file or directory (ignored)
[hpc3027:07438] mca: base: component_find: unable to open /usr/usc/openmpi/1.6.4/lib/openmpi/mca_btl_mx: libmyriexpress.
so: cannot open shared object file: No such file or directory (ignored)
myid = 0; mpid = 0: device used = 0; partial pi = 0.979926
myid = 0; mpid = 1: device used = 1; partial pi = 0.874671
myid = 1; mpid = 1: device used = 1; partial pi = 0.567582
myid = 1; mpid = 0: device used = 0; partial pi = 0.719409
PI = 3.141588
```
